

find_domains.py — Quick Start

Give it a CSV of company names → get a CSV with each company's website.

1. Install (one time)

Needs Python 3.8+. In your terminal, run:

```
pip install pandas requests beautifulsoup4 rapidfuzz tldextract
```

2. Prepare your input CSV

A CSV with a column named exactly **Company Name**. An optional **Domain URL** column (an existing website hint) helps but isn't required.

```
Company Name,Domain URL
Artistoholic Creations,artistoholic.com
Gifts N Hampers,
Bed Design Furniture,beddesign.in
```

3. Run it

Go to the folder holding the script + your CSV, then run:

```
python3 find_domains.py input.csv
# test on first 50 rows only:
python3 find_domains.py input.csv --limit 50
# if your name column is different:
python3 find_domains.py input.csv --company-col "Brand"
# continue an interrupted run:
python3 find_domains.py input.csv --resume
```

Must be online while it runs. Progress prints as it goes.

4. Your output

A new file **input_domains.csv** appears next to your input — all your original columns plus 5 new ones:

New column	What it contains
domain_url	The website found (blank if none).
domain_status	verified or not_found
confidence	High / Medium / Low (High = safe to use as-is)
matched_signals	Why it matched (technical clues).
candidates	Runner-up websites, separated by " ".

If you get an error about 'Company Name' not found

Your column has a different title. Add `--company-col "Your Title"` to the command, or rename the column in your CSV.
